Artificial Intelligence

Technology / Research snapshot: 18 Jun 2025

Artificial intelligence is the use of statistical models and computing systems to perform tasks that traditionally required human judgment, including perception, language, reasoning, and generation.

What is happening?

The industry is moving from model capability races into an infrastructure and distribution cycle. Capital expenditure is concentrating among a small group of platforms while enterprises test whether software agents can turn inference into durable productivity.

Why it matters

AI sits at the intersection of semiconductor demand, cloud economics, labor substitution, and national industrial policy. The first-order story is compute; the second-order story is who captures the value after models become abundant.

Risk assessment

The core risk is a mismatch between infrastructure commitments and monetized demand. Slower adoption, lower inference prices, or power constraints could compress returns before the new capacity earns out.

What to monitor

01 Hyperscaler capex and depreciation

02 Inference cost per million tokens

03 Enterprise seat expansion

04 Data-center power interconnect queues

Timeline

2022 Generative interfaces reach mass awareness

2023 Foundation model capital cycle accelerates

2024 Inference economics become the new battleground

2025 Agents move from demos into controlled workflows

Sources and limitations
